Module 3 Complete | Cloud Services & Web App Deployment

Day 11-15 of my internship at Codomax Digital Solutions is done, and I went from learning about the cloud to actually deploying on it.

This module was all about turning code into a real, live website - and understanding every piece in between.

WHAT I EXPLORED

- Compute: how VMs, containers and serverless differ, and when to use each
- Object storage: buckets, versioning, and why files shouldn't live in your database
- Managed databases: letting the provider handle backups, patching and uptime
- Virtual networking: public vs private subnets, security groups, load balancers
- IAM policies: least privilege, written as explicit JSON instead of blanket access
- Cloud monitoring: logs, metrics, alerts, and why a health check must test real dependencies

WHAT I LEARNED ABOUT DOING THIS SAFELY

Secrets belong in environment variables, never in code. A .gitignore stops .env and *.pem from ever reaching Git history - because once a secret is pushed, deleting it later does NOT remove it. And logging needs care: my app masks the database password as **** in every log line, so logs stay safe to share.

THE PROJECT: CLOUD NOTES

A Flask web app where you enter a name and a note, and it saves to a managed PostgreSQL database and lists the latest 50 notes.

The flow I deployed, end to end:

Application Code -> Cloud Compute -> Database / Storage -> Networking -> Live Web Application

Built with Flask, Flask-SQLAlchemy, Gunicorn and PostgreSQL

Endpoints: / , /health , /api/notes

25/25 automated tests passing before deploy

Input validation, HTML escaping, no secrets in the repo

MY BIGGEST TAKEAWAY

The same code ran on my laptop and in the cloud completely unchanged - the only difference was a set of environment variables. That clicked something for me: deploying to the cloud isn't about magic, it's about knowing where your configuration, your secrets and your data are supposed to live.

The hardest bugs weren't in my code - they were postgres:// vs postgresql://, a database in the wrong region, and a 502 that only made sense once I read the deploy logs. Cloud work is mostly troubleshooting, and that's a skill in itself.

Live app: <https://cloud-notes-app.onrender.com>

Health check: <https://cloud-notes-app.onrender.com/health>

The full Module 3 report is in the repository as both DOCX and PDF.

Huge thanks to the trainers and mentors at Codomax Digital Solutions for this module - the hands-on cloud demos made all of this click.

If you're on a cloud journey too, remember: read the logs first, and never trust a .env that isn't git-ignored.

Posting tips

1. Paste only the text between the two divider lines above - not this header table.
2. Paste the live app URL on its own line and wait for LinkedIn to generate a preview card.
3. Post between 8 AM and 10 AM for the best reach.
4. Reply to your own first comment with the GitHub link again - it lifts visibility.
5. Name the Render service exactly 'cloud-notes-app' so the URL matches this post.
